## **Network Flows: Blocking Flows**

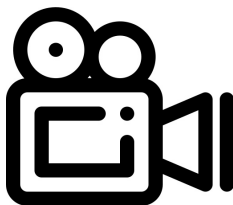

Lecture 6

# Recording of this Lecture

---

## This lecture will be recorded

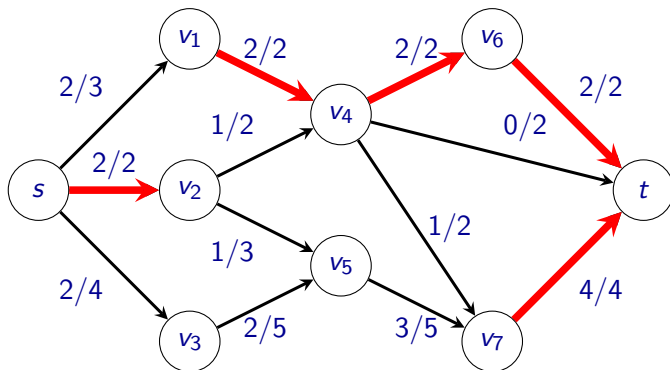

- ▶ Recording only of the lecturers by themselves.
- ▶ If there are questions from the audience, please make a clear signal if the microphone shall be muted.
- ▶ Our goal is to record the lecture, but it is no guarantee that each lecture will be recorded.

- ▶ Introduction to network flows
- ▶ Optimality criterion of augmenting paths
- ▶ Max-Flow Min-Cut Theorem
- ▶ Ford-Fulkerson algorithm:  $O(m \cdot M)$
- ▶ Edmonds-Karp algorithm:  $O(nm^2)$

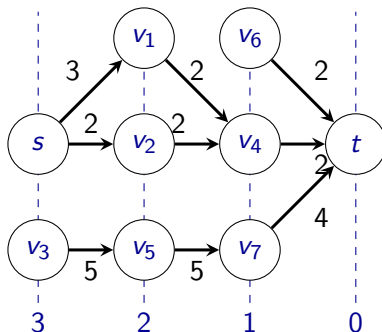

# Blocking Flows

A **blocking flow** in an  $s$ - $t$ -network  $\mathcal{N} = (V, E, c, s, t)$  is a feasible flow that saturates at least one edge on every  $s$ - $t$ -path in  $\mathcal{N}$ .

# Layered Networks

Let  $\mathcal{N} = (V, E, c, s, t)$  be an  $s$ - $t$ -network. The **layered network** of  $\mathcal{N}$  w.r.t.  $f$  is the  $s$ - $t$ -network  $\mathcal{N}' = (V, E', c', s, t)$ , where  $E' = \{(u, v) \in E_f \mid \delta_f(v) < \delta_f(u)\}$  and  $c'$  is the restriction of  $c_f$  to  $E'$ . For an  $i \in \mathbb{N}_0$ , the **layer**  $i$  of  $\mathcal{N}'$  is the set of vertices  $V_i = \{v \in V \mid \delta_f(v) = i\}$ .

# Computing Blocking Flows

## Lemma

A blocking flow in an acyclic  $s$ - $t$ -network  $\mathcal{N} = (V, E, c, s, t)$  with  $n$  vertices and  $m$  edges be computed in  $O(nm)$  time.

We use the following algorithm:

- ▶ Repeatedly start a DFS from  $s$  until reaching  $t$ .
- ▶ Whenever the DFS retreats over an edge  $e$ , remove  $e$ .
- ▶ Whenever reaching  $t$ , carry out an augmentation along the found  $s$ - $t$ -path. Remove all edges that become saturated by the augmentation.
- ▶ Stop when  $t$  is unreachable from  $s$ .

## Dinitz' Algorithm

1.  $f \leftarrow 0$
2. As long as  $f$  is not maximum, compute a blocking flow  $h$  in the layered network of  $\mathcal{N}_f$  w.r.t.  $f$ , and set  $f \leftarrow f + h$
3. Return  $f$

## Lemma

Every iteration of Dinitz' algorithm strictly increases  $\delta_f(s)$ .

## Theorem

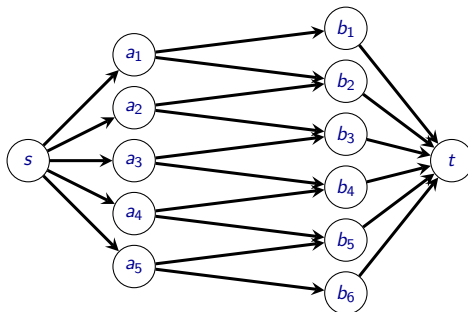

Dinitz' algorithm computes a maximum flow in an  $s$ - $t$ -network with  $n$  vertices and  $m$  edges in  $O(n^2m)$  time.

Edmond-Karp's algorithm only runs in  $O(nm^2)$  time.

# Simple $s$ - $t$ -Networks

An  $s$ - $t$ -network  $\mathcal{N} = (V, E, c, s, t)$  is **simple** if all capacities are integers, and for every  $v \in V \setminus \{s, t\}$ , at least one of the following conditions holds:

1. the capacities of the edges entering  $v$  sum up to at most 1, or
2. the capacities of the edges leaving  $v$  sum up to at most 1.

# Dinitz' Algorithm for Simple Networks

## Lemma

Dinitz' algorithm terminates after at most  $O(\sqrt{n})$  iterations when applied to a simple  $s$ - $t$ -network.

## Lemma

A blocking flow in the layered network  $\mathcal{L}$  of a simple  $s$ - $t$ -network  $\mathcal{N}$  w.r.t. an integral flow  $f$  in  $\mathcal{N}$  can be computed in  $O(n + m)$  time.

## Theorem

Dinitz' algorithm computes a maximum flow in a simple  $s$ - $t$ -network with  $n$  vertices and  $m$  edges in  $O(m \cdot \sqrt{n})$  time.

A maximum matching in a bipartite graph with  $n$  vertices and  $m$  edges can be computed in  $O(m \cdot \sqrt{n})$  time.
